Chess EDA

Owen G. Ward

Data

We first wish to investigate the properties of the scraped data. We focus for now on the Lichess data. We see that the vast majority of games in this dataset are Standard Chess, with the regular rules, etc.

```
## Variants of Chess in this data
table(lichess_data$Variant)
```

Antichess	Atomio	Chess960	Crazyhouse
1330	6522	16011	3138
Horde	King of the Hill	Racing Kings	Standard
832	954	1213	174157
Three-check			
1628			

Similarly, the most commonly played time control, across all formats of chess, is 180+0, which corresponds to 3 minute blitz games with no time increment.

```
head(sort(table(lichess_data$TimeControl), decreasing = TRUE))
```

```
180+0 30+0 60+0 15+0 300+0 60+1 38679 36456 33380 14757 14037 11652
```

Of standard games, we see that the majority are rated blitz and bullet games. These correspond to randomly playing available players on the site at a given time. This differs from tournaments, which make up a sizeable proportion of standard games also (and which might have different dynamics).

```
head(sort(table(lichess_data$Event), decreasing = TRUE))
```

```
Rated Bullet game Rated Blitz game Rated Chess960 game 31486 19385 13519
Rated Rapid game Daily HyperBullet Arena Hourly SuperBlitz Arena 9487 7278 5763
```

```
lichess_data %>% filter(Variant == "Standard") %>%
  group_by(Event) %>%
  count() %>%
  arrange(-n) %>%
  head()
```

```
# A tibble: 6 x 2

                            4436
```

The variable ratingDiff records how the ELO of both the black and white player changes based on the outcome of that game. Here these ELO scores are across the different event types, which may contain multiple time formats. For example, an ELO for Bullet play will change when both 1 minute and 30 second games are played, and also in both tournament and rated games.

Casual games don't change the rating, so we should probably treat them differently. Would likely have a different role in winner effects, etc. It is possible that Arena and tournament games also have different dynamics.

Initial Models

For the current initial analysis we will restrict to 1 minute rated bullet games, the most commonly played format in this dataset, with 13k games compared to 12k games of 30 second bullet and 12k games of 3 minute blitz.

```
## get initial dataset to use for analysis
  lichess_data %>%
    filter(Event == "Rated Bullet game") %>%
    group_by(TimeControl) %>%
    count() %>%
    arrange(-n)
# A tibble: 24 x 2

3 120+1
                3241
4 0+1
                 723
5 60+1
                 422
6 120+0
                 397
7 45+0
                 311
8 90+0
                  79
9 60+2
                  57
10 15+4
                  27
# ... with 14 more rows
  bullet_60 <- lichess_data %>%
    filter(Event == "Rated Bullet game") %>%
    filter(TimeControl == "60+0")
```

The top 25 players all play at least 80 games in this format, and across all games in this format we see relatively few draws. This is unsurprising as it it hard to end at a draw in these short time controls, when one player can lose on time.

```
head(sort(table(c(bullet_60$White, bullet_60$Black)), decreasing = TRUE), 25)
```

Multilevel Logistic Regression

Similar to Ding et al. (2021), we wish to fit a multilevel logistic regression to see if we can identify individual effects for chess players in this data. We will incorporate random effects for the player effects of the focal player in these games, along with random player level winner effects. We take common fixed effects for the effect of colour and the ELO difference.

We will identify focal players as those who were used to query the API, i.e the Username for each game. We only consider Rated 60 second bullet games here initially, and use the top 18 players, who all play at least 100 games of 1 minute rated bullet chess in this dataset.

We will consider the current history of an individual player as their win ratio in their past n games, where we will investigate the sensitivity of these results to different choices of n.

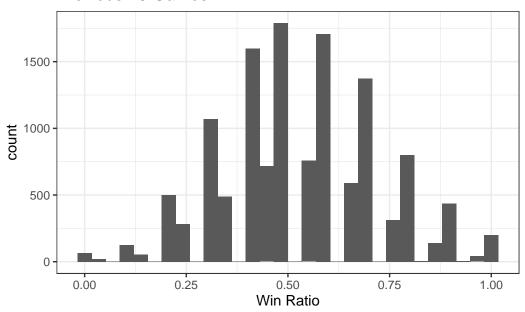

As a small percentage (less than 4%) of these games result in a draw, we will use these draws to get each players current win history, before then removing these from the logistic regression model. Initially we will choose the previous

$$n = 10$$

games for each player to compute the win ratio, or the average of all current games if the historic number of games played is less than 10.

We can see the distribution of the win ratio for these 18 players across all games in this sample.

Removing the drawn games, we have 12500 games involving these 18 focal players.

[1] 12578

STAN Model

Now we want to fit this multilevel logistic regression. Letting y_{ij} be the result of the *i*-th game by the *j*-th focal player, then the model we will consider is

$$P(y_{ij}=1) = \frac{1}{1+\exp(-(\alpha_j+\beta_j x_{ij}+\gamma z_{ij}))}$$

where:

- α_j is a player level random effect
- β_j is a player level random effect, accounting for the win ratio x_{ij}
- γ is a fixed effect of game level coefficients

We then partially pool the α and β coefficients, so

$$\alpha_i \sim \mathcal{N}(\mu_2, \tau_2)$$

$$\mu_2 \sim \mathcal{N}(0,5)$$

$$\tau_2 \sim \mathcal{C}auchy(0,5)$$

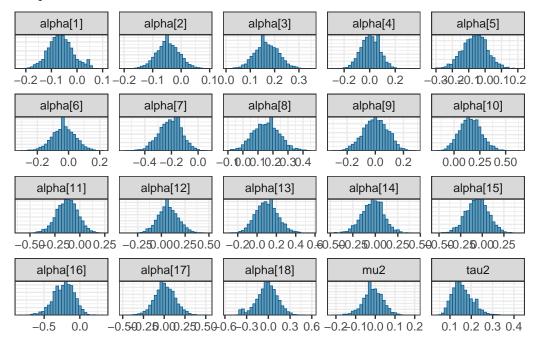

and similarly

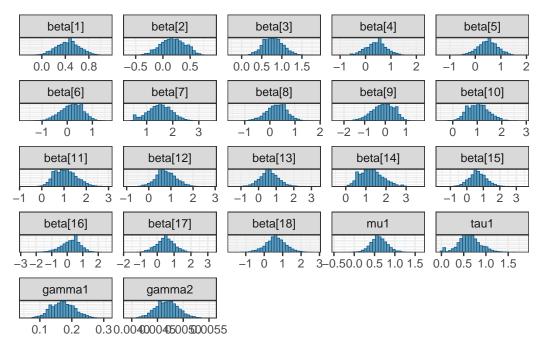

$$\begin{split} \beta_j &\sim \mathcal{N}(\mu_1, \tau_1) \\ \mu_1 &\sim \mathcal{N}(0, 5) \\ \tau_1 &\sim \mathcal{C}auchy(0, 5) \end{split}$$

We rescale the win ratio x_{ij} , by the average win ration of player j. This means β_j captures how a players win probability changes as their historic performance deviates from the overall average win ratio.

For z_{ij} we incorporate 2 covariates, namely the colour of the focal player and the ELO difference between the focal player and their opponent. So that means we have γ_1 , which tells us how the win probability changes in going from black to white, and γ_2 gives how the win probability changes as the focal player has a better ELO than their opponent.

Some of the output of this model is shown below, namely the empirical posteriors for each of the parameters.

The following metric (R-hat) indicates if the Bayesian model is converging. We would like values of smaller than 1.01 here, with values less than 1 possible in a sample.

Interpreting this output

Given this output, we can get the probability a player who is black will win against an equally ranked player, when their current win ratio is exactly their average will be $\frac{1}{1+\exp(-\alpha_j)}$. So a positive α_j indicates a player favoured to win even when playing black. The overall μ_2 tells us about the global probability of winning as black against an equally ranked opponent, which is just below 0, indicating a slightly less than 50% chance of winning. If a player is playing as white their win probability will be $\frac{1}{1+\exp(-(\alpha_j+\gamma_1))}$, so γ_1 being positive indicates the win probability increases when playing white, which makes sense. Playing white makes a player who has 50% chance of winning as black have approximately a 54% chance of winning with white. Wikipedia says the increase in win probability from playing white has been estimated to be 4-6% so quite similar.

Similarly, γ_2 tells us about how the ELO of the focal player being larger than their opponent influences their win probability. The estimate here indicates that a large ELO difference makes a player very likely to win, as would be expected. For example, a player who has a 50% chance of winning against an opponent with the same ELO will have about a 61% chance of winning against an opponent with an ELO score 100 points lower.

How big are these effects

We then want to quantify how much these estimated effects change the expected win probability. We have seen the size of the effects above for the non history parameters. The largest posterior mean for a $\beta \approx 1.56$. Since the normalized win proportion is between -0.6 and 0.6, that means that for a game where this player has a 50% chance of winning with a normalized average win proportion of 0, if their normalized win proportion is 0.5, the win probability will increase by $\approx 19\%$. This would occur, for example, if they win 50% of their total games but have won all 10 of their last 10. This is a similar size effect to the increase in win probability which would come from playing an opponent with an ELO ranking that is 170 points lower.

Similarly, a normalized win history 0.25 above average corresponds to a difference of approximately 80 in ELO scores.

The underlying parameter μ_1 has posterior mean of 0.606. A normalised win history of 0.25 with a winner effect of this size would increase the win probability by about 4%, a similar effect as playing as white instead of black, all other covariates being equal.

Probability of Positive Winner Effects

For each of these players, we can use the posterior draws to estimate the posterior probability that $\beta > 0$, i.e that there is a positive effect.

```

We can then use this metric to compare how these winner effects change as we change both the length of the history and the type of games used.

Varying History

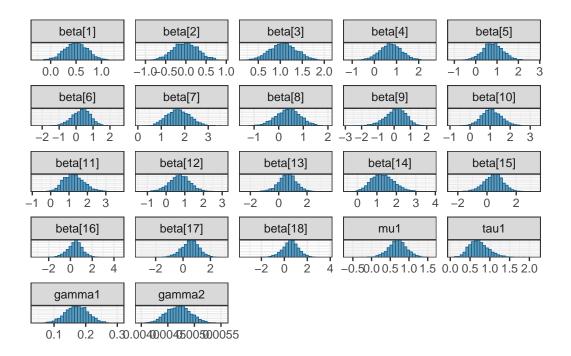

We can refit this using varying numbers of games for the current win ratio.

We first consider instead using the previous 5 games.

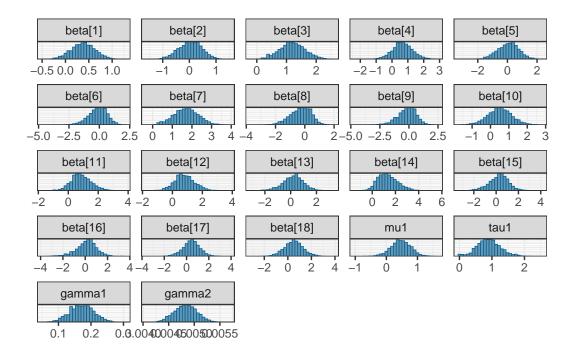

```

The posterior of these effects does seem to change somewhat as we vary the history. This also seems to vary from player to player. We also consider the previous 20 games.

beta[1] beta[2] beta[3] beta[4] beta[5] beta[6] beta[7] beta[8] 0.98500 0.48875 1.00000 0.93500 0.95050 0.71825 1.00000 0.78550 beta[9] beta[10] beta[11] beta[12] beta[13] beta[14] beta[15] beta[16] 0.58150 0.98450 0.99250 0.90575 0.84425 0.99450 0.75750 0.74075 beta[17] beta[18] 0.79950 0.78950

Finally, we consider the previous 50 games also.

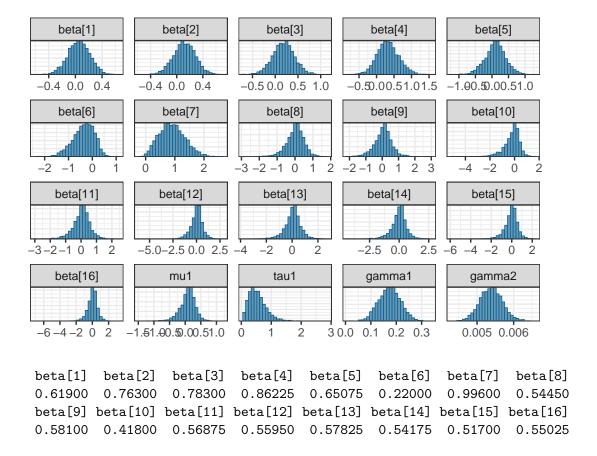

beta[1] beta[2] beta[3] beta[4] beta[5] beta[6] beta[7] beta[8] 0.54750 0.92900 0.54350 0.99800 0.86075 0.45950 0.99950 0.36850 beta[9] beta[10] beta[11] beta[12] beta[13] beta[14] beta[15] beta[16] 0.78425 0.44150 0.90825 0.89425 0.61375 0.96375 0.64850 0.59100 beta[17] beta[18] 0.73125 0.73800

The size of the winner effects does appear to decrease as you look at a longer amount of previous games. Unlikely to play more than 50 games in a row maybe? It does appear that the mean for τ_2 increases as we consider longer histories.

Longer Games

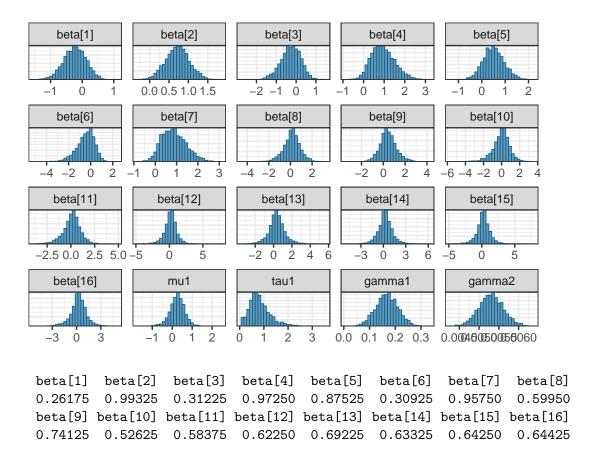

In the above example we considered only rated 60 second bullet games. We will now instead consider rated 3 minute blitz games, and fit the same model. This would indicate how the effect might change as we vary the length of the games considered. We have 12k total such blitz games. We will use the same players as were considered for the bullet data, of which 16 play blitz games and only 7 play more than 100 blitz games. This leads to 9000 games.

We first consider using the previous 5 games as the history. We remove draws from the outcomes, but use them for the history.

When we instead consider blitz games there seems to be considerably less evidence for these winner effects, with many of the β parameters centered around 0 now. This seems reasonable, indicates smaller effects in longer games.

We can also repeat this with the previous 20 blitz games as an example also. We only consider 13 players now who have more than 20 blitz games from the original selection.

This seems to mirror the smaller number of blitz games quite closely.

Comments

- Are there any other variables we should be controlling for here?
- How data dependent is this result? Should investigate the performance across different players, the strength of the winner effect as a function of the ELO of a player, etc.

Streaks

One of the other interesting components of this data is the performance of a player after they draw the previous game, compared to when they won or lost the previous game. There are a small number of draws is this data set that we can use to investigate this. We just get the proportion of results in the next game, for both the bullet and blitz data.
